Reference: Nusrat Jahan Jui(IT-18039)

Experiment no: 11

Experiment Name: Implementation of FIFO page replacementAlgorithm.

Theory:

This is the simplest page replacement algorithm. In this algorithm, the operating system keeps track of all pages in the memory in a queue, the oldest page is in the front of the queue. When a page needs to be replaced page in the front of the queue is selected for removal. Page replacement happens when a requested page is not in memory (page fault) and a free page cannot be used to satisfy the allocation, either because there are none, or because the number of free pages is lower than some threshold.

Implementation:

- 1. Start the process
- 2. Declare the size with respect to page length
- 3. Check the need of replacement from the page to memory
- 4. Check the need of replacement from old page to new page in memory
- 5. Forma queue to hold all pages
- 6. Insert the page require memory into the queue
- 7. Check for bad replacement and page fault
- 8. Get the number of processes to be inserted
- 9. Display the values
- 10. Stop the process

Working Process:

Code for FIFO page replacementAlgorithm-

```
#include<stdio.h>
int main()
       int i,j,n,a[50],frame[10],no,k,avail,count=0;
       printf("\n ENTER THE NUMBER OF PAGES:\n");
       scanf("%d",&n);
       printf("\n ENTER THE PAGE NUMBER :\n");
       for(i=1;i\leq n;i++)
       scanf("%d",&a[i]);
       printf("\n ENTER THE NUMBER OF FRAMES :");
       scanf("%d",&no);
       for(i=0;i< no;i++)
       frame[i]= -1;
               j=0;
               printf("\tref string\t page frames\n");
for(i=1;i\leq n;i++)
               {
                      printf("%d\t\t",a[i]);
                       avail=0;
                       for(k=0;k<no;k++)
if(frame[k]==a[i])
                              avail=1;
                       if (avail==0)
                              frame[j]=a[i];
                              j=(j+1)%no;
                              count++;
                              for(k=0;k<no;k++)
                              printf("%d\t",frame[k]);
       }
                       printf("\n");
       }
               printf("Page Fault Is %d",count);
               return 0;
```

Output:

```
C:\Users\Admin\Documents\jui_lab_11.exe
                                                                       X
ENTER THE NUMBER OF PAGES:20
ENTER THE PAGE NUMBER :7 0 1 2 0 3 0 4 2 3 0 3 2 1 2 0 1 7 0 1
ENTER THE NUMBER OF FRAMES :3

Page Fault Is 15
Process returned 0 (0x0)
                               execution time : 50.003 s
Press any key to continue.
```

Discussion:

The above algorithm has been implemented using C language. It is simple and easy to implement and understand. Initially all slots are empty, so when 7,0,1 came they are allocated to the empty slots-3page faults. Then 2 comes, it is not available in memory so it replaces the oldest page slot i.e 7->1 Page Fault. 0 is already in memory so 0 Page fault. Continuing the process we finally get page fault=15
